Unit Tests

- Unit tests seek to guarantee that each individual component works in isolation, without depending on databases, APIs, or file systems.
- It consists of writing a secondary block of code whose purpose is to execute a specific method and verify a correct result.
- It aims to test only the internal logic of the methods, and if they require external data, it is mocked/simulated. Furthermore, their only possible results are true and false.

JUnit

- It is a framework for Java.
- @Test: Indicates the "what" to the development environment or compiler.
- Framework: Template with tools or libraries to start a program from scratch.
- Assertions: Built-in function that compares the value the program was supposed to give with the one it actually gave.
- Test runner: Runs all the tests in the project and shows green if it worked or red if it failed.
